Choroideremia: \textit{CHM} Gene Deletion/Duplication

\textbf{Test Code:} DCHMX  
\textbf{Turnaround time:} 2 weeks  
\textbf{CPT Codes:} 81228 x1

\section*{Condition Description}

Choroideremia is an X-linked disorder causing chorioretinal degeneration with an incidence of 1 in 50,000. Mutations in the \textit{CHM} (Xq21.2) gene cause this condition.

The characteristic feature of choroideremia is the progressive chorioretinal degeneration in affected males. In males, the symptoms range from night blindness to peripheral visual field loss with central vision preserved until late in life. About 30\% of males have posterior subcapsular cataracts. Carrier females are usually asymptomatic but the chorioretinal degeneration can be picked up by fundus examination. They also exhibit mild symptoms after the second decade of life. In cases of skewed X-inactivation, females can develop symptoms similar to affected males.

Both sequencing and deletion/duplication mutations have been described in the \textit{CHM} gene. A founder splice site mutation in exon 13 is common in the Finnish population. Rarely, \textit{CHM} can be part of a more severe contiguous gene deletion syndrome involving Xq21.

For patients with suspected choroideremia, sequence analysis is recommended as the first step in mutation identification. For individuals in whom mutations are not identified by full gene sequencing, deletion/duplication analysis is appropriate.

\section*{Genes}

\textit{CHM}

\section*{Indications}

This test is indicated for:

- Confirmation of a clinical diagnosis of choroideremia in an individual in whom sequence analysis was negative.
- Carrier testing in adults with a family history of choroideremia in whom sequence analysis was negative.

\section*{Methodology}

DNA isolated from peripheral blood is hybridized to a CGH array to detect deletions and duplications. The targeted CGH array has overlapping probes which cover the entire genomic region.

\section*{Detection}

Detection is limited to duplications and deletions. Sequencing and whole/ partial gene deletions account for approximately 60-95\% of cases. The CGH array will not detect point or intronic mutations. Results of molecular analysis must be interpreted in the context of the patient's clinical and/or biochemical phenotype.

\section*{Specimen Requirements}

\textit{Submit only 1 of the following specimen types}

\section*{Type: DNA, Isolated}

\textbf{Specimen Requirements:}  
Micrortainer\textsuperscript{3}\textsuperscript{4}  
Isolation using the Perkin Elmer\textsuperscript{TM} Chemagen\textsuperscript{TM} Automated Extraction method or Qiagen\textsuperscript{TM} Puregene kit for DNA extraction is recommended.

\textbf{Specimen Collection and Shipping:}  
Refrigerate until time of shipment in 100 ng/\(\mu\)L in TE buffer. Ship sample at room temperature with overnight delivery.

\section*{Type: Whole Blood (EDTA)}

\textbf{Specimen Requirements:}  
EDTA (Purple Top)
Infants and Young Children (2 years of age to 10 years old): 3-5 ml
Older Children & Adults: 5-10 ml
Autopsy: 2-3 ml uncotted cord or cardiac blood

Specimen Collection and Shipping:
Ship sample at room temperature for receipt at EGL within 72 hours of collection. Do not freeze.

Special Instructions
Sequence analysis is required before deletion/duplication analysis by targeted CGH array. If sequencing is performed outside of EGL Genetics, please submit a copy of the sequencing report with the test requisition.

Related Tests
- Sequence analysis of the CHM gene is available and is required before deletion/duplication analysis.
- Custom diagnostic mutation analysis (KM) is available to family members if mutations are identified by targeted mutation testing or sequencing analysis.
- Prenatal testing is available only for known familial mutations to individuals who are confirmed carriers of mutations. Please contact the laboratory genetic counselor to discuss appropriate testing prior to collecting a prenatal specimen.
